

1. Abstract - Introduction We propose a decentralized reputation system that can replace the word-of-mouth, stars- and review-based systems. The basic idea is that a member A trusts her friends with a certain value (with a 1/2 multisig), thus risking to lose their value. When A wants to transfer value V to a (maybe previously unknown) member B, A asks the system if she trusts B enough to transfer this value to B. The system will search throughout the network for trust paths that begin from A and reach B and add up to V and will answer whether the proposed transaction is within the trust capabilities of A towards B. If the answer is positive, it means that transferring value V to B will not raise the risk for A to lose their value. Note: we use Bitcoin terminology.

Definitions

- Direct trust from A to B, $DTr_{A \rightarrow B}$
Total amount of value that exists in 1/{A,B} multisigs in the utxo, where the money is deposited by A
- B steals x from A
B steals value x from A when B reduces the $DTr_{A \rightarrow B}$ by x. This makes sense when $x \leq DTr_{A \rightarrow B}$.
- Honest (passive) strategy
A member A is said to follow the honest (passive) strategy if for any value x that is stolen from her, she substitutes it by stealing from others that trust her:

$$\begin{cases} x & \text{if } \sum_{B \in \text{members}} DTr_{B \rightarrow A} \geq x \\ \sum_{B \in \text{members}} DTr_{B \rightarrow A} & \text{if } \sum_{B \in \text{members}} DTr_{B \rightarrow A} < x \end{cases}$$

or simply $\min(x, \sum_{B \in \text{members}} DTr_{B \rightarrow A})$.

- Indirect trust from A to B $Tr_{A \rightarrow B}$
Value that A will lose if B steals the maximum amount she can steal (all her incoming trust) and everyone else follows the honest (passive) strategy.

Theorems

- $Tr_{A \rightarrow B} = \text{MaxFlow}_{A \rightarrow B}$ (Treating trusts as capacities)
- Trust transfer theorem (flow terminology)
Let s source, t sink,
 $X_s = \{x_{s \rightarrow 1}, \dots, x_{s \rightarrow n}\}$ outgoing flows from s,
 $X_t = \{x_{1 \rightarrow t}, \dots, x_{m \rightarrow t}\}$ incoming flows to t,
 $U_s = \{u_{s \rightarrow 1}, \dots, u_{s \rightarrow n}\}$ outgoing capacities from s,
 $U_t = \{u_{1 \rightarrow t}, \dots, u_{m \rightarrow t}\}$ incoming capacities to t,
V the value to be transferred.
Nodes apart from s, t cannot create or consume flow.
Obviously $\text{maxFlow} = F = \sum_{i=1}^n x_{t \rightarrow i}$.

We create a new graph where

(a) $\sum_i u'_{s \rightarrow i} = F - V$

(b) $u'_{s \rightarrow i} \leq x_{s \rightarrow i}$

We will now prove that $\maxFlow' = F' = F - V$.

(a) It is impossible to have $F' > F - V$ because $F' \leq \sum u'_{s \rightarrow i} = F - V$.

(b) It is impossible to have $F' < F - V$.

Let i be a node such that $x_{s \rightarrow i} > 0$ and $I = \{(i, j) \in E\}$ the set of direct trusts outgoing from i . In the initial graph we have $x_{s \rightarrow i} = \sum_j x_{i \rightarrow j}$, $F = \sum_i x_{s \rightarrow i}$ and in the new graph we have $x'_{s \rightarrow i} = u'_{s \rightarrow i} \leq x_{s \rightarrow i}$, $F' = \sum_i x'_{s \rightarrow i}$, $x_{i \rightarrow j} \leq u_{i \rightarrow j} = u'_{i \rightarrow j} \forall j, i$. We can construct a set $X'_i = \{x'_{i \rightarrow j}\}$ of flows such that $x'_{i \rightarrow j} \leq x_{i \rightarrow j}$ and $\sum_j x'_{i \rightarrow j} = x'_{s \rightarrow i}$. This shows that there is a possible flow such that $F' = F - V$, so the maxFlow algorithm will not return a flow less than $F - V$.

Example construction:

$x'_{i \rightarrow j} = x_{i \rightarrow j} \forall j \in \{1, \dots, k\}$ with k such that

i. $\sum_{j=1}^k x_{i \rightarrow j} \leq x'_{s \rightarrow i}$ and

ii. $\sum_{j=1}^{k+1} x_{i \rightarrow j} > x'_{s \rightarrow i}$

$x'_{i \rightarrow (k+1)} = x'_{s \rightarrow i} - \sum_{j=1}^k x'_{i \rightarrow j}$

$x'_{i \rightarrow j} = 0 \forall j \in \{k+2, \dots, |X'_i|\}$
